

Test Method

I will summarize the test method as below.

1. There is a method to check how many bacteria die over time by placing a blood medium in which bacteria or microorganisms have been cultivated or grown in a small chamber, and placing a DrCl activated a day ago around it.

2. To see how well Dr.Cl catch airborne bacteria, you need a large chamber with a sprinkler-like device. This is a method to check how much airborne bacteria die until falling on the floor while installing DrCl onto the ceiling.

It is very difficult to obtain such a large chamber, and even if it is, the experiment cost will be huge.
